(The current divides and divides again in an effort to follow the path of least resistance.) After that, it's a simple matter to calculate the voltage drops in each resistor using $V = IR$ and the power dissipated using $P = VI$. No part of this problem is difficult by itself, but since the circuit is so complex we'll be quite busy for a little while.

When solving any combinational resistor circuit that is made up of resistors in series and parallel branches, the first step we need to take is to identify the simple series and parallel resistor branches and replace them with equivalent resistors.

Combination of Resistors Resistors can be combined in two ways: series and parallel. Combination of more than one resistor is called equivalent resistor. We first look at the resistors in series: Resistors in Series a. In this types of circuit, amount of currents passing through the resistors are equal and this current comes from the battery, $i=i_1=i_2=i_3$ b.

Question TitleCircuit Problems III Two resistors are wired in series. The second resistor has twice the resistance as the first. Current passes through the combination. Compared to the current through the first resistor, the current through the second resistor is: A. Twice the magnitude B. The same C. Half the magnitude D. Quarter of the magnitude

Replace series or parallel resistors with their equivalent resistor. Continue, moving left until a single equivalent resistor represents the entire resistor network. The location in question is the input voltage source, so we start the simplification process way over on the far right, and work our way toward the source.
